

TITLE OF THE INVENTION

WIRELESS COMMUNICATION APPARATUS, WIRELESS
COMMUNICATION METHOD, AND COMPUTER PROGRAM

CROSS-REFERENCE TO RELATED APPLICATIONS

5 This application is based upon and claims the
benefit of priority from prior Japanese Patent
Application No. 2003-092507, filed March 28, 2003,
the entire contents of which are incorporated herein by
reference.

10 BACKGROUND OF THE INVENTION

1. Field of the Invention

 The present invention relates to an apparatus,
method, and computer program for providing a plurality
of images stored in a storage to another wireless
15 communication apparatus through wireless
communications.

2. Description of the Related Art

 Specifications for a wireless communication scheme
called Bluetooth (trade mark) and standardized by
20 the Bluetooth SIG (Special Interest Group) relate
to wireless devices, communication protocols, and
application models. The specifications for application
models are called profiles. For example, profiles for
file transfer, exchange of electronic business card
25 information, and exchange of photographic electronic
images are called a file transfer profile, an object
push profile, and a basic imaging profile. Each of

these profiles includes specifications for data exchange. These profiles are characterized by utilizing IrOBEX (or simply OBEX). The OBEX protocol is a communication protocol that specifies a method of exchanging electronic information as objects. The OBEX protocol has a connection setting function, a connection clearing function, an object transmission function, an object reception function, and the like. Presently, OBEX specifies the following commands.

COMMANDS	MEANING
Connect	choose your partner, negotiate capabilities
Disconnect	signal the end of the session
Put	send an object
Get	get an object
SetPath	modifies the current path on the receiving side
Abort	abort the current operation

The term "connection" has the same meaning as the above "session". In the description below, the term "connection" will be used instead of the expression "session". The OBEX is described in detail in "Infrared Data Association, IrDA Object Exchange Protocol (IrOBEX) with Published Errata, Version 1.2, April 1999" and is incorporated herein by reference.

The basic imaging profile (hereinafter referred to

as "BIP") conforms to the OBEX protocol, described above. Version 1.0 of the BIP defines six use scenarios. These six use scenarios are called features and include image push, image pull, remote display, remote camera, advanced image print, and automatic archive. Each of these features specifies a procedure for exchanging still images between devices and a procedure for transmitting and receiving data utilizing the OBEX protocol.

A detailed description of each feature is described in BIP specifications laid open by the Bluetooth SIG. According to the BIP specification, devices are classified into initiators and responders in accordance with their rolls. For example, with the image push feature, the initiator is defined to make request for the start of an image transmission and the like. The responder is defined to receive images transmitted by the initiator. With the remote camera feature, the initiator is defined to make request for acquisition of images. The responder is defined to provide images. The initiator and the responder are also described in the BIP specifications in detail.

The remote camera feature, one of the BIP features, specifies four functions including GetMonitoringImage, GetImageProperties, GetImage, and GetLinkedThumbnail. These functions allow the initiator to acquire information on images from

the responder under the OBEX protocol. The BIP specifications describe the configurations of an OBEX request and response packets for each function, an exchange procedure, and the like in detail.

5 The responder for the remote camera feature is assumed to be a device such as a digital camera which has a function of capturing images.

The BIP specifies the six features as described above. However, devices in accordance with the BIP do not support all of these six features. Different devices may have different support forms. For example, a certain device in accordance with the BIP supports only the image push and pull features but not the other features. Another devices in accordance with the BIP supports only the image push and remote display features.

To enable certain device to browse and acquire images saved in another device, it is essential that both of these devices, acting as an initiator and a responder, respectively, support the BIP image pull feature. For example, even if a plurality of images are saved in responder comprising the remote camera feature, initiator that does not comprise the image pull feature but only the remote camera feature cannot browse or acquire these images.

It is contemplated that if a device comprising only the remote camera feature comprises an FTP (File

Transfer Protocol) function, it may use the FTP
function to acquire images. However, the FTP treats
images simply as files without distinguishing them
from other kinds of information. In view of users'
5 operability, it is preferable to treat images as
images. For example, an image providing mechanism is
preferably implemented with which an operator of
certain device can cause images saved in another device
to be displayed on a screen of the operator's device
10 and select one of the images to be acquired. Even if a
remote camera feature operation screen is improved and
made more sophisticated so as to display images, it is
not available if the FTP is used to acquire files.

BRIEF SUMMARY OF THE INVENTION

15 The present invention is directed to provide
an apparatus, method and computer program that
contributes to allowing an image providing function
based on wireless communications to be utilized and
operated easily and efficiently.

20 According to an aspect of the present invention,
there is provided a wireless communication apparatus
which provides a plurality of images stored in
a storage to an initiating wireless communication
apparatus through wireless communications. A reception
25 unit receives an image acquisition request message
transmitted from the initiating wireless communication
apparatus. The message conforms to a camera control

protocol for exchanging information relating to images. A selection unit selects, in response to the image acquisition request message, one of the plurality of images stored in the storage. A transmission unit then
5 transmits a response message to the initiating wireless communication apparatus in accordance with the camera control protocol. Information relating to the one of the plurality of images that is selected by the selection unit is contained in the response message.

10 BRIEF DESCRIPTION OF THE SEVERAL VIEWS OF THE DRAWING

FIG. 1 is a block diagram schematically showing a wireless communication apparatus according to embodiments of the present invention;

15 FIG. 2 is a diagram showing a topology of communication between the wireless communication apparatus according to the embodiments of the present invention and another wireless communication apparatus;

FIG. 3 is a flowchart showing a part of a specific process procedure according to a first embodiment;

20 FIG. 4 is a flowchart showing the other parts of the specific process procedure according to the first embodiment;

FIG. 5 is a flowchart showing a part of a specific process procedure according to a second embodiment of
25 the present invention;

FIG. 6 is a flowchart showing the other parts of the specific process procedure according to the second

embodiment;

FIG. 7 is a flowchart showing a part of a specific process procedure according to a third embodiment of the present invention;

5 FIG. 8 is a flowchart showing the other parts of the specific process procedure according to the third embodiment;

FIG. 9 is a flowchart showing a specific process procedure according to a fourth embodiment of the present invention;

10

FIG. 10 is a flowchart showing a part of a specific process procedure according to a fifth embodiment of the present invention;

FIG. 11 is a flowchart showing the other parts of the specific process procedure according to the fifth embodiment;

15

FIG. 12 is an illustration showing a sixth embodiment of the present invention;

FIG. 13 is a diagram schematically showing a wireless communication apparatus according to the sixth embodiment;

20

FIG. 14 is a diagram schematically showing another wireless communication apparatus according to the sixth embodiment;

FIG. 15 is an illustration of an operation screen displayed by the display device of the wireless communication apparatus shown in FIG. 14; and

25

FIG. 16 shows a display example of the operation screen shown in FIG. 15, in the case where detected peripheral apparatuses are displayed on the screen.

DETAILED DESCRIPTION OF THE INVENTION

5 (First Embodiment)

A first embodiment will be described below with reference to FIGS. 1 to 4. FIG. 1 is a block diagram schematically showing a wireless communication apparatus (hereinafter simply referred to as
10 "apparatus") according to embodiments of the present invention. An apparatus 1 comprises a wireless transmission and reception function using, for example, Bluetooth as a wireless communication scheme and can carry out wireless transmission and reception in
15 accordance with the Bluetooth communication protocol. The apparatus 1 is assumed to support Basic Imaging Profile (hereinafter referred to as BIP) services.

As shown in FIG. 1, the apparatus 1 includes an image storage unit 100, an image conversion unit
20 200, an image acquisition request analysis unit 300, an image selection unit 400, and a wireless communication (Bluetooth) management unit 500. The apparatus 1 comprises general hardware elements such as a CPU, a memory, and a system bus. However, for the convenience
25 of description, their illustration is omitted.

An SDP (Service Discovery Protocol) and an OBEX (Object Exchange Protocol) are assumed to be included

in a protocol stack for the wireless communication management unit 500, including a radio transmission and reception device that uses Bluetooth as a communication method as well as the Bluetooth communication protocol.

5 This enables the wireless communication management unit 500 to communicate with surrounding other Bluetooth apparatuses in accordance with an SDP or OBEX communication procedure. For example, upon receiving a request for acquisition of service information from

10 another Bluetooth apparatus in accordance with the SDP, the apparatus 1 responds its service information. On the other hand, upon receiving a request for an OBEX connection, the apparatus 1 sets an OBEX connection. Upon receiving a request for an OBEX disconnection,

15 the apparatus 1 clears the OBEX connection.

The wireless communication management unit 500 receives an OBEX request packet from another Bluetooth apparatus. The received OBEX request packet is analyzed by the image acquisition request analysis

20 unit 300 in the apparatus 1. On the basis of the results of analysis of this OBEX request packet, the image acquisition request analysis unit 300 gives an instruction to the image selection unit 400 or the image conversion unit 200 and prepares and transmits

25 information on the requested image to the wireless communication management unit 500, as required. Here, the "information on an image" means data (image data)

on the image itself, an identifier for uniquely identifying the image, data on the image obtained by subjecting the image to image processing, and information on the attributes (properties) of the
5 image. The "information on an image" will hereinafter be referred to be as "image information".

Upon receiving inputted image information from the image acquisition request analysis unit 300, the wireless communication management unit 500 constructs
10 an appropriate OBEX response packet containing the inputted image information. The wireless communication management unit 500 then returns this packet through wireless communication to the Bluetooth apparatus that has issued the OBEX request packet. The apparatus 1
15 according to the present embodiment can exchange data through the wireless communication management unit 500 in response to a request from another Bluetooth apparatus.

The image storage unit 100 has a function of
20 electronically storing and retaining image data. It can provide the image data to the image selection unit 400 in response to an instruction from the image unit 400. If for example, the image storage unit 100 stores and retains image data in a file format, it may
25 provide the image selection unit 400 with all data from an image file or pointer information on the image file stored in the image storage unit 100.

The image selection unit 400 has a function of selecting one of the images stored and retained in the image storage unit 400 in accordance with an instruction from the image acquisition request analysis unit 300. The image selection unit 400 also has a function of outputting image information on the selected image to the image acquisition request analysis unit 300. The image selection unit 400 may provide the image acquisition request analysis unit 300 with all data from an image file or pointer information on the image file stored in the image storage unit 100.

The image conversion unit 200 has a function of converting the size or format of an image. It also has a function of providing the image acquisition request analysis unit 300 with a converted image upon receiving image data and information on a converted size or format inputted by the image acquisition request analysis unit 300. The image acquisition request analysis unit 300 may input to the image conversion unit 200 all data from an image file or pointer information on the image file stored in the image storage unit 100. As converted image data, the image conversion unit 200 may provide all data from an image file to the image acquisition request analysis unit 300. Alternatively, the image conversion unit 200 may provide the image acquisition request analysis unit 300 with pointer information on the file if the image data

is temporarily stored in the image storage unit 100 in a file format.

5 The apparatus 1 according to various embodiments of the present invention, described below, is assumed to be a responder supporting the remote camera feature. As described above, with the remote camera feature, assumed to be a control protocol for the exchange of images picked up by a camera, the initiator issues a request for acquisition of an image. The responder
10 provides the image. The responder supporting the remote camera feature is assumed to be an apparatus such as a digital camera which has a capture function. The present invention may be implemented as an apparatus that does not comprise any image capture
15 functions but only an image providing function according to the present invention based on the remote camera feature. Such the apparatus may be assumed to be one of various apparatuses, including portable information recording apparatuses, cellular telephones,
20 personal information managers (PIMs), personal computers, and Internet electric appliances.

 The image acquisition request analysis unit 300 has a function of correctly determining, upon receiving inputted information on an OBEX request
25 packet from the wireless communication management unit 500, whether the request is for the GetMonitoringImage, GetImageProperties, GetImage, or GetLinkedThumbnail

function, which is specified in the remote camera feature, one of the BIP features. The image acquisition request analysis unit 300 instructs the image selection unit 400 to select one image data and then receives the selected image data from the image selection unit 400. The image acquisition request analysis unit 300 also examines the image data selected by the image selection unit 400 to acquire property information such as size and format information.

The image acquisition request analysis unit 300 also outputs image information to the wireless communication management unit 500. The image acquisition request analysis unit 300 may output to the wireless communication management unit 500 the image data itself selected by the image selection unit 400, image data converted by the image conversion unit 200, or the property information acquired by the image acquisition request analysis unit 300.

FIG. 2 is a diagram showing a topology of communication between an apparatus 9 and the apparatus 1, which are wirelessly coupled together. The apparatus 9 is an initiator that supports the remote camera feature. The apparatus 1, in which the present invention is embodied, is a responder that supports the remote camera feature as described above. Description will be given below of operations of embodiments according to the present invention on the basis of

an example of data exchange between the apparatus 9 and the apparatus 1.

5 The image storage unit 100 is assumed to store and retain N images consisting of images 1 to N. An "image x" is an identifier that identifies an image stored in the image storage unit 100. If for example, the image storage unit 100 retains three image files names "Kobe.jpg", "Osaka.jpg", and "Kyoto.jpg", then N=3 and the file "Kobe.jpg" is an image 1, the "Osaka.jpg" is
10 an image 2, and the file "Kyoto.jpg" is an image 3.

 First, the apparatus 9 discovers the apparatus 1 in accordance with the Bluetooth communication protocol. Then, the apparatus 9 retrieves a communication service for the apparatus 1 and then
15 sets a connection between the apparatus 9 and the apparatus 1 in accordance with the OBEX protocol. Since the apparatus 9 supports the remote camera feature, it can set an OBEX connection used to exchange data in accordance with the remote camera feature.
20 The apparatus 9 can also transmit a GetMonitoringImage request to the apparatus 1.

 The wireless communication management unit 500 receives the GetMonitoringImage request from the apparatus 9, having set the OBEX connection.
25 The wireless communication management unit 500 then notifies the image acquisition request analysis unit 300 that it has received the request. Upon receiving

the notification indicating the reception of the
GetMonitoringImage request, the image acquisition
request analysis unit 300 outputs an image selection
request signal to the image selection unit 400. Upon
5 receiving the inputted image selection request signal,
the image selection unit 400 randomly selects one of
the images 1 to N, stored and retained in the image
storage unit 100. The image selection unit 400 then
outputs image information on the selected image k to
10 the image acquisition request analysis unit 300.

Upon receiving the inputted image data on the
image k, the image acquisition request analysis unit
300 requests that the image conversion unit 200 create
a thumbnail image of the image k. The image conversion
15 unit 200 creates a thumbnail image of the image k in
accordance with the request. It then outputs the
thumbnail image to the wireless communication
management unit 500.

Upon receiving the inputted thumbnail image
20 information, the wireless communication management unit
500 creates a response packet in accordance with the
OBEX protocol. The wireless communication management
unit 500 transmits the response corresponding to the
GetMonitoringImage request to the apparatus 9. This
25 response packet contains data on the thumbnail image.
Upon receiving all of the response corresponding to
the GetMonitoringImage request from the apparatus 1,

the apparatus 9 can generate and display a thumbnail image from the thumbnail image data contained in the received response.

The GetMonitoringImage request contains a
5 parameter called StoreFlag. The value of the StoreFlag (true or false value, true = 1, false = 0) indicates whether or not to request an identifier for the photographed (captured) image. If the StoreFlag is 1, the image acquisition request analysis unit 300 stores
10 and retains the image information on the image k in an internal buffer. The buffer preferably includes a memory (cache) that can perform a fast read or write operation. Furthermore, if the StoreFlag is 1, the response corresponding to the GetMonitoringImage
15 request contains the identifier (called ImageHandle) for the image k. After the response corresponding to the GetMonitoringImage request, the apparatus 9 transmits a GetImageProperties request, GetImage request, or GetLinkedThumbnail request containing the
20 identifier (ImageHandle) for the image k. Upon being notified through the wireless communication management unit 500 that one of these requests has been received, the image acquisition request analysis unit 300 outputs the image information on the image k to the wireless
25 communication management unit 500. In particular, upon receiving a GetImage request or GetLinkedThumbnail request, the image acquisition request analysis unit

300 uses the image conversion unit 200 to convert the size or format of the image k and outputs the converted image information to the wireless communication management unit 500, as required.

5 Upon receiving the image information on the image k corresponding to the GetProperties request, GetImage request, or GetLinkedThumbnail request from the image acquisition request analysis unit 300, the wireless communication management unit 500 creates a response
10 packet in accordance with the OBEX protocol. The wireless communication management unit 500 transmits a response corresponding to one of these requests to the apparatus 9. This response packet contains the image information on the image k. Upon receiving all
15 of the response corresponding to the request from the apparatus 1, the apparatus 9 can acquire the image information on the image k contained in the received response.

 FIG. 3 is a flowchart showing a part of a specific
20 process procedure according to the first embodiment. FIG. 4 is a flowchart showing the other parts of this process procedure. It is assumed that an OBEX connection based on the BIP remote camera feature has already been set.

25 As shown in FIG. 3, first, in step S302, an OBEX request packet is received. In step S303, it is determined whether or not the received OBEX packet is

for a disconnect request. If the packet is for a disconnect request, the connection to the initiator is cleared to finish the process. If the packet is not for a disconnect request, the process proceeds to
5 step S304.

In step S304, it is determined whether or not the received OBEX packet is for a GetMonitoringImage request. If the packet is for a GetMonitoringImage request, the process proceeds to step S306 and
10 otherwise to step S401 in FIG. 4. Steps S306 to S311 are a response process corresponding to the GetMonitoringImage request and correspond to the process relating to image provision according to the present embodiment, described above.

15 Subsequently, the image k is randomly selected from the images 1 to N (step S306). A thumbnail image of the selected image k is generated (step S307). In step S307, a thumbnail image need not be generated every time the image k is selected. If a separate
20 thumbnail image is already retained, this image data may be utilized as it is.

Then, in step S309, it is determined whether or not the StoreFlag contained in the GetMonitoringImage request has a value of 1. If the StoreFlag has a value
25 of 1, then in step S310, the information on the image k is stored. Then, the process proceeds to step S311. If the StoreFlag does not have a value of 1, step S310

is skipped and the process proceeds to step S311.

In step S311, a GetMonitoringImage response containing the thumbnail image of the image k is returned to the initiator. The process then returns to
5 step S302. However, in step S311, if the StoreFlag has a value of 1, the response is returned together with the identifier (ImageHandle) for the image k.

FIG. 4 shows a process procedure executed when a request other than GetMonitoringImage is received.
10 If it is determined that the received OBEX request packet is not for a GetMonitoringImage request, it is determined whether or not the request contains the identifier (ImageHandle) for the image k (step S401). The request is assumed to be one of GetImageProperties,
15 GetImage, and GetLinkedThumbnail. If the request does not contain the identifier (ImageHandle) for the image k, the process proceeds to step S414 to return a response containing error information. Otherwise, the process described below is executed depending on the
20 type of the request.

If the request is GetImageProperties (step S402), property information on the image k is acquired (step S403). A GetProperties response is generated and returned which contains the property information on
25 the image k (step S404).

If the request is GetImage (step S405), image specification information such as a size and a format

is referenced and checked which is contained in the
GetImage request (step S406). In accordance with
the image specification information, the image k is
converted into an image k' (step S407). If the image
5 k' cannot be created (step S408), a GetImage response
containing error information is returned (step S409).
On the other hand, if the image k' can be correctly
created, a GetImage response containing the image k' is
returned (step S410).

10 If the request is GetLinkedThumbnail (step S411),
a thumbnail image of the image k is created (step
S412). A GetLinkedThumbnail response containing the
thumbnail image of the image k is returned (step S413).

Upon finishing the process procedure to
15 be executed when the request other than
GetMonitoringImage, described above, is received,
the procedure returns to the process of receiving
an OBEX request packet (step S302 in FIG. 3).

In the present embodiment, the image selection
20 unit 400 randomly selects one of the images 1 to N
retained in the image storage unit 100. However, the
images may be sequentially selected in the order of,
for example, the image 1, the image 2, ...

According to the first embodiment, described
25 above, the apparatus 1 can operate as a responder
in accordance with the BIP remote camera feature.
The apparatus 1 can utilize the functions specified in

the remote camera feature to provide information on image data retained in the apparatus 1 to the apparatus 9, acting as an initiator and also comprising the BIP remote camera feature.

5 (Second Embodiment)

A second embodiment of the present invention adds functions to the image acquisition request analysis unit 300, described in the first embodiment. As in the case with the first embodiment, in the second
10 embodiment, the image storage unit 100 is assumed to store N images consisting of images 1 to N. Upon receiving a notification indicating that a GetMonitoringImage request has been received, the image acquisition request analysis unit 300 outputs an image
15 selection request signal to the image selection unit 400. Upon receiving the inputted image unit request signal, the image selection unit 400 randomly selects one of the images 1 to N stored and retained in the image storage unit 100. The image selection unit 400
20 outputs image information on the selected image k to the image acquisition request analysis unit 300. Upon receiving the inputted image information on the image k, the image acquisition request analysis unit 300 issues a request for creation of a thumbnail image
25 of the image k to image conversion unit 200. The image conversion unit 200 creates a thumbnail image of the requested image k. The image conversion unit 200

then outputs the thumbnail image to the wireless communication management unit 500.

In the second embodiment, the image acquisition request analysis unit 300 is configured to store the image information on the image k for a specified time. This image information contains the thumbnail image of the image k. The specified time is, for example, five seconds. If the image acquisition request analysis unit 300 is notified again within the specified time that a GetMonitoringImage has been received, it outputs the stored thumbnail image information on the image k without outputting an image selection request signal to the image selection unit 400.

FIG. 5 is a flowchart showing a part of a specific process procedure according to the second embodiment. FIG. 6 is a flowchart showing the other parts of this specific process procedure. It is assumed that an OBEX connection based on the BIP remote camera feature has already been set.

As shown in FIG. 5, in step S502, an OBEX request packet is received. In step S503, it is determined whether or not the received OBEX packet is for a disconnect request. If the packet is for a disconnect request, the connection to the initiator is cleared to finish the process. If the packet is not for a disconnect request, the process proceeds to step S504.

In step S504, it is determined whether or not

the received OBEX packet is for a GetMonitoringImage request. If the packet is for a GetMonitoringImage request, the process proceeds to step S505 in FIG. 6 and otherwise to step S515. Step S515 is a process
5 procedure executed when the request other than GetMonitoringImage is received, and is similar to that shown in FIG. 4.

Steps S505 to S514, shown in FIG. 6, are a response process corresponding to the
10 GetMonitoringImage request and correspond to the process relating to image provision according to the second embodiment, described above.

In step S505, it is determined whether or not a timer has timed out. The timer does not actually
15 time out under initial conditions. However, it is exceptionally determined that timeout has occurred, and the process proceeds to step S506 to set the timer. In other words, in the process for the first GetMonitoringImage request in the process procedure,
20 step S505 is skipped.

Subsequently, the image k is randomly selected from the images 1 to N (step S508). A thumbnail image of the selected image k is generated (step S509). The generated thumbnail image is internally stored
25 and retained in step S511. In step S513, information on the image k is stored, and the process proceeds to step S514.

In step S514, a GetMonitoringImage response containing the thumbnail image of the image k is returned to the initiator. The process then returns to step S502. If in step S514, the StoreFlag is 1,
5 the response is returned together with the identifier (ImageHandle) for the image. If in step S505, it is not detected that the timer has timed out, steps S506 to S513, described above, are skipped. Then, the thumbnail image of the image k internally stored and
10 retained for the specified time is used as it is. The GetMonitoringImage response containing the thumbnail image is returned.

In the present embodiment, the image selection unit 400 randomly selects one of the images 1 to N
15 retained in the image storage unit 100. However, the images may be sequentially selected in the order of, for example, the image 1, the image 2, ...

According to the second embodiment, described above, the apparatus 1 can use the functions specified
20 in the remote camera feature to provide information on image data retained in the apparatus 1 to the apparatus 9, acting as the initiator and comprising the BIP remote camera feature, as in the case with the first embodiment. Furthermore, if the apparatus 1 receives a
25 request for acquisition of an image from the initiator apparatus 9, it undergoes a lighter processing load for image selection than in the first embodiment.

Moreover, if the initiator apparatus 9 continuously issues GetMonitoringImage requests, the apparatus 1 according to the present embodiment responds with the same image for a specified time until the timer times out. Therefore, the user can check the same image for the specified time. This is preferable in implementing an image browsing process.

(Third Embodiment)

A third embodiment of the present invention adds functions to the image selection unit 400, described in the first embodiment. As in the case with the first embodiment, in the third embodiment, the image storage unit 100 is assumed to store N images consisting of images 1 to N. Every time the wireless communication management unit 500 notifies the image acquisition request analysis unit 300 that a GetMonitoringImage request has been received, the image acquisition request analysis unit 300 outputs an image unit request signal to the image selection unit 400.

In the third embodiment, the image selection unit 400 has a function of detecting that the wireless communication management unit 500 has generated an OBEX connection. The image selection unit 400 also has a timer function and a function of storing time information.

The image acquisition request analysis unit 300 inputs an image selection request to the image

selection unit 400. Then, if the image selection request signal has been inputted for the first time after the OBEX connection has been generated, then the image selection unit 400 outputs information on the image 1 of the images 1 to N, stored and retained in image storage unit 100, to the image acquisition request analysis unit 300. The image selection unit 400 also stores the time when it has received the image selection request signal, as first time information. It also stores the time when it has received the image selection request signal, separately as the time when a GetMonitoringImage request has been started. Then, the image selection unit 400 initializes the value of an image number used as internal information, to 0.

Upon receiving the second image selection request signal, the image selection unit 400 stores the time of the reception as second time information if the image number has a value of 0. The image selection unit 400 compares the first time information with the second time information. If the difference between these two times is T1 seconds or shorter, the image selection unit 400 outputs the information on the image 1 to the image acquisition request analysis unit 300. Otherwise, the image selection unit 400 outputs information on image 2 stored and retained in the image storage unit 100 to the image acquisition request analysis unit 300. The image selection unit 400 stores

the second time information as the first time information.

A similar process is executed for the third and subsequent image selection request signals. After
5 outputting the image information on the image k to the image acquisition request analysis unit 300 and upon receiving an inputted image selection request signal, the image selection unit 400 stores the time of the reception as the second time information if the image
10 number has a value of 0. The image selection unit 400 compares the first time information with the second time information. If the difference between these two times is T_1 seconds or shorter, the image selection unit 400 outputs the information on the image k to
15 the image acquisition request analysis unit 300. Otherwise, the image selection unit 400 outputs information on image k+1 stored and retained in the image storage unit 100 to the image acquisition request analysis unit 300. If $k=N$, the image selection unit
20 400 outputs the information on the image 1 to the image acquisition request analysis unit 300 as the image k+1.

The image selection unit 400 compares the time when the x-th image selection request signal has been inputted with the time when the GetMonitoringImage
25 request has been started. If the difference between these two times is $(x-1) \times T_2$ is shorter, the image selection unit 400 determines that the apparatus 9

periodically transmits a GetImage request, to start the timer at this point in time. If it is assumed that the image selection unit 400 has outputted information on image j to the image acquisition request analysis unit 300 before the start of the timer, j is stored as the image number. Every time timeout occurs, the image selection unit 400 adds one to the value of the image number. It is assumed that if $j=N$, the value of $j+1$ is 1.

Upon receiving an inputted image selection request signal, the image selection unit 400 outputs information on an image m of the images 1 to N , stored and retained in the image storage unit 100, to the image acquisition request analysis unit 300 if the image number has a value of m (m is not 0). If the image number has a value of m that is other than 0, the image selection unit 400 avoids comparing the first time information with the second time information and storing the time information upon receiving an inputted image selection request signal as described previously.

FIG. 7 is a flowchart showing a part of a specific process procedure according to the third embodiment.

FIG. 8 is a flowchart showing the other parts of this specific process procedure. It is assumed that an OBEX connection based on the BIP remote camera feature has already been set. In this flowchart, if the image selection unit 400 compares the time when the x -th

image selection request signal has been inputted with the time when the GetMonitoringImage request has been started and the difference between these two times is $(x-1) \times T2$ is shorter as described above, then x has a value of 2. In the present example, the expressions $T1$ and $T2$ seconds are used. However, it is allowable that $T1 > T2$ and that $T1 = 5$ seconds and $T2 = 3$ seconds as a specific example.

As shown in FIG. 7, in step S601, the value of a variable k and a value for the image information on the image k are initialized to 0. Furthermore, time information 1 and time information 2 are each initialized. Then, in step S602, an OBEX request packet is received. In step S603, it is determined whether or not the received OBEX packet is for a disconnect request. If the packet is for a disconnect request, the connection to the initiator is cleared to finish the process. If the packet is not for a disconnect request, the process proceeds to step S604.

In step S604, it is determined whether or not the received OBEX packet is for a GetMonitoringImage request. If the packet is for a GetMonitoringImage request, the process proceeds to step S607 and otherwise to step S605. Step S605 is a process procedure executed when the request other than GetMonitoringImage is received, and is similar to that shown in FIG. 4.

Steps S607 to S625 (see FIG. 8) are a response process corresponding to the GetMonitoringImage request and correspond to the specific process relating to image provision according to the third embodiment.

5 First, in step S607, the current time information is stored as the time information 1. Then, it is determined whether or not the GetMonitoringImage request in step S604 has been inputted for the first time after the OBEX connection has been set
10 (step S608). If it is determined that the first GetMonitoringImage request has been inputted, the process proceeds to step S609. Otherwise, the process proceeds to step S610 in FIG. 8.

 In step S610 in FIG. 8, it is determined whether
15 or not the image number is 0. If the image number is not 0, the process proceeds to step S612. In step S612, it is determined whether or not timer has timeout. If in step S612, it is detected that the timer has timed out, one is added to the value of the
20 image number and the value of the variable k is set equal to the value of the image number(step S616). Subsequently, the timer is started (step S617). If in step S616, the image number has a value of N+1, this value is returned to 1.

25 In step S610, described above, if the image number is determined to be 0, it is determined in step S611 whether or not the time difference between the time

information 1 and the time information 2 is T2 or shorter (step S611). If the time difference is T2 or shorter, the value of the image number is set equal to the value of the variable k (step S613). In step S617,
5 the timer is started. On the other hand, if it is determined in step S611 that the time difference is longer than T2, then it is determined whether or not the time difference between the time information 1 and the time information 2 is T1 or shorter (step S614).
10 If the time difference is T1 or shorter, the time information 1 is copied to the time information 2 (step S615). On the other hand, in step S614, if it is determined that the time difference is longer than T1, the time information 1 is copied to the time
15 information 2 (step S609). Then, one is added to the value of the variable k (step S616). If in step S618, the variable k has a value of N+1, this value is returned to 1.

Then in step S619, the image k is selected from
20 the images 1 to N (step S 619). A thumbnail image of the selected image k is generated (step S620). Subsequently in step S623, it is determined whether or not the StoreFlag contained in the GetMonitoringImage request has a value of 1. If the StoreFlag has a value
25 of 1, then in step S624, information on the image k is stored. The process then proceeds to step S625. If the StoreFlag does not have a value of 1, the

process proceeds to step 625 by skipping step S624.

In step S625, a GetMonitoringImage response containing the thumbnail image of the image k is returned to the initiator. The process returns to
5 step S602. In step S625, if the StoreFlag is 1, the response is returned together with the identifier (ImageHandle) for the image k.

According to the third embodiment, described above, the apparatus 1 can use the functions specified
10 in the remote camera feature to provide information on image data retained in the apparatus 1 to the apparatus 9, acting as the initiator and comprising the BIP remote camera feature, as in the case with the first embodiment. Furthermore, it can be determined whether
15 or not the initiator apparatus 9 continuously transmits image acquisition requests. Specifically, the responder apparatus 1 measures the time intervals between image acquisition requests from the initiator apparatus 9. If the time intervals are short in the
20 above case, e.g. 3 to 5 seconds, i.e. image acquisition requests are generated at a high speed, the responder detects this situation in step S611 or S614, described above. The responder then provides the initiator apparatus 9 with the same image (here, a thumbnail
25 image). The initiator apparatus 9, which has requested provision of an image utilizing a GetMonitoringImage request as described above, is provided with the same

image at fixed time intervals regardless of the number of requests per unit time. This makes it possible to appropriately browse images provided by the responder apparatus 1 without missing.

5 (Fourth Embodiment)

A fourth embodiment of the present invention adds functions to the image acquisition request analysis unit 300, described in the first embodiment. As in the case with the first embodiment, in the fourth
10 embodiment, the image storage unit 100 is assumed to store N images consisting of images 1 to N.

In the fourth embodiment, the image acquisition request analysis unit 300 is assumed to be able to store image information on the image k and to store
15 no image information in its initial conditions. This image information contains a thumbnail image of the image k. When the wireless communication management unit 500 notifies the image acquisition request analysis unit 300 that a GetMonitoringImage has been
20 received, the image acquisition request analysis unit 300 checks the value of the StoreFlag contained in the GetMonitoringImage request. In the present embodiment, when GetMonitoringImage requests are continuously transmitted, if at a certain time, the StoreFlag
25 contained in the GetMonitoringImage has a value of 1 and a thumbnail image has already been transmitted in response to the last request, a thumbnail image of

the image k and the image information on the image k, the original of the thumbnail image, are provided. The process procedure of the present embodiment will be described below.

5 [Process executed if the StoreFlag has a value of 0]

If the StoreFlag contained in the GetMonitoringImage request has a value of 0, the image acquisition request analysis unit 300 initializes the internally stored image information. The image acquisition request analysis unit 300 then outputs an
10 image selection request signal to the image selection unit 400. Upon receiving the inputted image selection request signal, the image selection unit 400 randomly selects one of the images 1 to N stored and retained in the image storage unit 100. The image selection unit
15 400 then outputs the image information on the selected image k to the image acquisition request analysis unit 300.

Upon receiving the inputted image information on the image k, the image acquisition request analysis
20 unit 300 requests that the image conversion unit 200 create a thumbnail image of the image k. Then, the image conversion unit 200 creates a thumbnail image of the requested image k and then outputs the thumbnail
25 image and the value of the StoreFlag (in this case, 0) to the wireless communication management unit 500. The image acquisition request analysis unit 300 internally

stores the image information on the image k. This image information contains the thumbnail image of the image k.

5 Upon receiving the inputted thumbnail image information and StoreFlag value, the wireless communication management unit 500 creates a response packet in accordance with the OBEX protocol.

The wireless communication management unit 500 then transmits a response corresponding to the
10 GetMonitoringImage request. If the StoreFlag has a value of 0, the response packet contains only the data on the thumbnail image.

[Process executed if the StoreFlag has a value of 1]

15 If the StoreFlag contained in the GetMonitoringImage request has a value of 1, the image acquisition request analysis unit 300 outputs an image unit request signal to the image selection unit 400 if its internally stored image information is in the initial conditions. Upon receiving the inputted image
20 selection request signal, the image selection unit 400 randomly selects one of the images 1 to N stored and retained in the image storage unit 100. The image selection unit 400 then outputs the image information on the selected image k to the image acquisition
25 request analysis unit 300.

 Upon receiving the inputted image information on the image k, the image acquisition request analysis

unit 300 requests that the image conversion unit 200
create a thumbnail image of the image k. Then, the
image conversion unit 200 creates a thumbnail image of
the requested image k and then outputs the thumbnail
5 image and the value of the StoreFlag (in this case, 1)
to the wireless communication management unit 500.
The image acquisition request analysis unit 300
internally stores the image information on the image k.
This image information contains the thumbnail image of
10 the image k.

On the other hand, if the internally stored image
information is not in the initial conditions, i.e. the
image information on the image k is associated with
contents, the image acquisition request analysis unit
15 300 outputs the internally stored thumbnail image of
the image k and the internally stored StoreFlag value,
to the wireless communication management unit 500.
Upon receiving the inputted thumbnail image information
and StoreFlag value, the wireless communication
20 management unit 500 creates a response packet in
accordance with the OBEX protocol. The wireless
communication management unit 500 then transmits the
response corresponding to the GetMonitoringImage
request to the apparatus 9. The response packet
25 transmitted if the StoreFlag has a value of 1 contains
data on the thumbnail image and the identifier (called
ImageHandle) for the image k.

FIG. 9 is a flowchart showing a specific process procedure according to the fourth embodiment. It is assumed that an OBEX connection based on the BIP remote camera feature has already been set.

5 As shown in FIG. 9, in step S801, a condition flag is initialized to 0. Then, in step S802, an OBEX request packet is received. In step S803, it is determined whether or not the received OBEX packet is for a disconnect request. If the packet is for a
10 disconnect request, the connection to the initiator is cleared to finish the process. If the packet is not for a disconnect request, the process proceeds to step S804.

 In step S804, it is determined whether or not
15 the received OBEX packet is for a GetMonitoringImage request. If the packet is for a GetMonitoringImage request, the process proceeds to step S805 and otherwise to step S806. Step S806 is a process procedure executed when the request other than
20 GetMonitoringImage is received, and is similar to that shown in FIG. 4.

 Steps S805 to S817 are a response process corresponding to the GetMonitoringImage request and correspond to the process relating to image provision
25 according to the fourth embodiment, described above. First, in step S805, it is determined whether or not the StoreFlag contained in the GetMonitoringImage

request has a value of 0.

If the StoreFlag is determined to have a value of 0, the image k is randomly selected from the images 1 to N (step S807). A thumbnail image of the selected
5 image k is generated (step S809). In step S809, the thumbnail image need not always be generated. If a separate thumbnail image is already retained, its image data may be utilized as it is. Then, information on the image k is stored (step S810). The condition
10 flag is set to 1 (step S811). Then in step S812, the GetMonitoringImage response containing the thumbnail image of the image k is returned to the initiator.

On the other hand, if in step S805, the StoreFlag is determined not to have a value of 0 but to have a
15 value is 1, then it is determined in step S808 whether or not the condition flag is 1. In this case, if the condition flag is 1, the process proceeds to step S817. On the other hand, if the flag is not 1 (i.e. the flag is 0), the same process procedure as that of steps S807
20 to S811 is executed. The process then proceeds to step S817.

In step S817, a GetMonitoringImage response containing the thumbnail image of the image k is returned to the initiator. Then, the process returns
25 to step S802. In step S817, the response is returned together with the identifier (ImageHandle) for the image k.

In the present embodiment, the image selection unit 400 randomly selects one of the images 1 to N retained in the image storage unit 100. However, the images may be sequentially selected in the order of, for example, the image 1, the image 2, ...

In the first embodiment, it is contemplated, if the initiator apparatus 9, displaying and checking the thumbnail image acquired from the apparatus 1, requests that the apparatus 1 acquire image information on the original image (i.e. the image from which the thumbnail image has been generated) corresponding to the currently displayed thumbnail image, the initiator apparatus 9 may be provided with image information on an image different from the currently displayed one. However, according to the fourth embodiment, described above, the true-or-false value of the StoreFlag contained in the GetMonitoringImage request is referenced. Then, when the StoreFlag has a true value (with negative logic, a false value), the cached image k and its image information are selected without randomly selecting the image k. Consequently, the initiator apparatus 9 can reliably acquire image information corresponding to the original image for which the acquisition request has been made.

(Fifth Embodiment)

A fifth embodiment of the present invention adds functions to the image acquisition request analysis

unit 300, described in the fourth embodiment. As in the case with the fourth embodiment, in the fifth embodiment, the image storage unit 100 is assumed to store N images consisting of images 1 to N. In the
5 fifth embodiment, the image acquisition request analysis unit 300 is assumed to be able to store image information on the image k and its thumbnail image and to store no contents in the initial conditions. Furthermore, the image acquisition request analysis
10 unit 300 internally retains a timer. When the wireless communication management unit 500 notifies the image acquisition request analysis unit 300 that a GetMonitoringImage request has been received, the image acquisition request analysis unit 300 checks the value
15 of the StoreFlag contained in the GetMonitoringImage request. In this point, this embodiment is similar to the fourth embodiment, described above.

FIG. 10 is a flowchart showing a part of a specific process procedure according to the fifth
20 embodiment. FIG. 11 is a flowchart showing the other parts of this specific process procedure. It is assumed that an OBEX connection based on the BIP remote camera feature has already been set.

As shown in FIG. 10, in step S901, the condition
25 flag is initialized to 0. Then, in step S902, an OBEX request packet is received. In step S903, it is determined whether or not the received OBEX packet is

for a disconnect request. If the packet is for a disconnect request, the connection to the initiator is cleared to finish the process. If the packet is not for a disconnect request, the process proceeds to
5 step S904.

In step S904, it is determined whether or not the received OBEX packet is for a GetMonitoringImage request. If the packet is for a GetMonitoringImage request, the process proceeds to step S905 and
10 otherwise to step S917. Step S917 is a process procedure executed when the request other than GetMonitoringImage is received, and is similar to that shown in FIG. 4.

Steps S905 to S916 (see FIG. 11) are a response process corresponding to the GetMonitoringImage request
15 and correspond to the process relating to image provision according to the fifth embodiment, described above.

In step S905, it is determined whether or not the
20 timer has timed out. The timer does not actually time out under the initial conditions. However, it is exceptionally determined that timeout has occurred, and the process proceeds to step S906 to set the timer. In other words, in the process for the first
25 GetMonitoringImage request in the process procedure, step S905 is skipped.

In step S907, it is determined whether or not the

StoreFlag contained in the GetMonitoringImage request has a value of 0. If the StoreFlag has a value of 1, the initiator has requested not only a thumbnail image of the image k but also the image k itself (the
5 original image of the thumbnail image).

If the StoreFlag is determined to have a value of 0, the image k is randomly selected from the images 1 to N (step S910). A thumbnail image of the selected image k is generated (step S911). In step S912,
10 information on the image k is stored. Then, the condition flag is set to 1 (step S913).

On the other hand, if in step S907, the StoreFlag is determined not to have a value of 0, then it is determined whether or not the condition flag is 1 (step
15 S909). In this case, if the condition flag is 1, the process proceeds to step S916. If the flag is not 1, the process then proceeds to step S910.

In step S914, it is determined again whether or not the StoreFlag contained in the GetMonitoringImage request has a value of 0. If the StoreFlag has a value
20 of 0, the process proceeds to step S915. In step S915, a GetMonitoringImage response containing the thumbnail image of the image k is returned to the initiator. Then, the process returns to step S902. On the other
25 hand, if in step S914, the StoreFlag contained in the GetMonitoringImage request is determined not to have a value of 0, the process proceeds to step S916.

In step S916, the GetMonitoringImage response containing the thumbnail image of the image k is returned to the initiator. The process then returns to step S902. If in step S916, the StoreFlag is 1,
5 the response is returned together with the identifier (ImageHandle) for the image k. If in step S905, it is not detected that the timer has timed out, steps S906 to S913, described above, are skipped. Then, the thumbnail image of the image k internally stored and
10 retained for a specified time is used as it is. The GetMonitoringImage response containing the thumbnail image or the GetMonitoringImage response containing the thumbnail image of the image k and the identifier (ImageHandle) for the image k is returned depending on
15 the value of the StoreFlag.

In the present embodiment, the image selection unit 400 randomly selects one of the images 1 to N retained in the image storage unit 100. However, the images may be sequentially selected in the order of,
20 for example, the image 1, the image 2, ...

According to the fifth embodiment, described above, the initiator apparatus 9 can acquire a thumbnail image and its original image properly associated with each other, as in the case with the
25 fourth embodiment, described above. Moreover, the processing load for image selection can be reduced. Furthermore, if the initiator apparatus 9 continuously

issues GetMonitoringImage requests, the apparatus 1 according to the present embodiment responds with the same image for a specified time until the timer times out. Therefore, the user can check the same image for the specified time. This is preferable in implementing an image browsing process.

(Sixth Embodiment)

A sixth embodiment of the present invention will be described below. The sixth embodiment of the present invention relates to a specific example in which services are realized using an apparatus comprising the functions of the present invention. Description will be given of the exchange of image data between an apparatus 1000 and an apparatus 9000. The apparatus 1000 has functions described in the first to fifth embodiments and the apparatus 9000 has a function of acquiring image data from the apparatus 1000 and displaying it.

As shown in FIG. 12, the apparatus 9000 and the apparatus 1000 are connected together via a wireless link including a Bluetooth communication path c. The apparatus 1000 is assumed to provide services and to be placed in a shop A. On the other hand, the apparatus 9000 is assumed to be portable, which acquires services and can be carried by a user with him or her.

FIG. 13 schematically shows the configuration of the apparatus 1000. The apparatus 1000 comprises

the functions of the apparatus 1, shown in the first embodiment, as well as one of the image providing methods described above in the first to fifth embodiments. Thus, the apparatus 1000 can utilize the Bluetooth to transmit and receive data. Specifically, a communication protocol layer is implemented in the apparatus 1000 and contains communication protocols including the Bluetooth OBEX. The apparatus 1000 supports the BIP. The apparatus 1000 further comprises a remote camera feature specified in the BIP and operates as a responder.

The apparatus 1000 specifically includes hardware such as a personal computer incorporating the Bluetooth, a PDA (Personal Digital Assistant) incorporating the Bluetooth, a personal computer into which a Bluetooth card is inserted, a PDA into which a Bluetooth card is inserted, or a hard disk incorporating the Bluetooth. It is also assumed that software is installed in the apparatus 1000 to implement a Bluetooth protocol layer and the image providing method according to the present invention.

FIG. 14 shows the configuration of the apparatus 9000. The apparatus 9000 comprises a wireless communication management unit 9500, an image acquisition request unit 9600, a storage unit 9100, and a display unit 9700. A communication protocol layer that includes the Bluetooth OBEX is implemented in the

apparatus 9000. The apparatus 9000 supports the BIP over the Bluetooth OBEX. The apparatus 9000 further comprises the remote camera feature specified in the BIP and operates as an initiator. The apparatus 9000
5 specifically includes hardware that can be carried by the user with him or her, such as a PDA (Personal Digital Assistant) incorporating the Bluetooth and comprising a display area such as a liquid crystal screen, a PDA into which a Bluetooth card is inserted,
10 or a cellular phone incorporating the Bluetooth. It is also assumed that software is installed in the apparatus 1000 to implement a Bluetooth protocol layer and the image acquiring method. The display unit 9700 controls a display device 9001 which corresponds to
15 those provided in a PDA, cellular phone, or the like. FIG. 15 shows an example of an operation screen displayed on the display device 9001.

In the example of the operation screen provided by the display unit 9700 as shown in FIG. 15, when the
20 user operates a discovery button B1 (for example, with a PDA, a button displayed on the screen is tapped, or with a cellular phone, a hardware button is associated with the button on the displays unit), the display unit 9700 outputs a discovery request to the image
25 acquisition request unit 9600. Upon receiving the inputted discovery request, the image acquisition request unit 9600 outputs a peripheral-apparatus

discovery request to the wireless communication management unit 9500. Upon receiving the inputted peripheral-apparatus discovery request, the wireless communication management unit 9500 executes a process of discovering Bluetooth peripheral apparatuses and a process of retrieving services provided by the peripheral apparatuses. The wireless communication management unit 9500 thus detects the peripheral Bluetooth apparatuses as candidates for apparatuses operating as a responder for the BIP remote camera feature. The wireless communication management unit 9500 outputs information on the detected apparatuses to the image acquisition request unit 9100. Upon receiving the inputted apparatus information, the image acquisition request unit 9600 stores it in the storage unit 9100. The stored apparatus information includes device addresses and parameter information required to connect to a responder service for the remote camera feature. The image acquisition request unit 9600 causes the detected apparatus names to be displayed in a display area A through the display unit 9700 to inform the user of the name of the peripherally present apparatuses as candidates for a connection destination. FIG. 16 shows that the detected peripheral apparatuses D1 to D4 are displayed in the display area A. If in the apparatus 1000, the friendly name of the Bluetooth is set as "shop A information", the "shop A

information" shown in FIG. 16 corresponds to the apparatus 1000.

In the example of the operation screen provided by the display unit 9700 as shown in FIG. 15, when
5 the user selects the apparatus 1000 and operates a connection button B3, the display unit 9700 outputs a connection request to the image acquisition request unit 9600. Upon receiving the inputted connection request, the image acquisition request unit 9600
10 utilizes the wireless communication management unit 9500 to set a connection between the apparatus 1000 and the OBEX using a connection parameter stored in the storage unit 9100. Once the OBEX connection is set, the image acquisition request unit 9600 issues a
15 GetMonitoringImage request with a store flag set to 0, to acquire a monitoring image from the apparatus 1000. Upon acquiring the monitoring image, the image acquisition request unit 9600 causes the monitoring image acquired to be displayed in the
20 display area A via the display unit 9700. The image acquisition request unit 9600 repeatedly issues a GetMonitoringImage request with the store flag set to 0 and causes the monitoring image acquired to be displayed in the display area A via the display
25 unit 9700.

In the example of the operation screen provided by the display unit 9700 as shown in FIG. 15, when

a process is started to acquire a monitoring image,
an acquisition button B2 is enabled. When the
user operates the acquisition button B2, the
image acquisition request unit 9600 issues
5 a GetMonitoringImage request with the store flag set
to 1, to acquire ImageHandle, an identifier for
an image, from the apparatus 1000. Upon acquiring the
ImageHandle, the image acquisition request unit 9600
issues a GetImage request containing the ImageHandle
10 acquired, to acquire an image corresponding to the
ImageHandle, from the apparatus 1000. Upon acquiring
the corresponding image, the image acquisition request
unit 9600 stores the image acquired in the storage
unit 9100.

15 In the example of the operation screen provided by
the display unit 9700 as shown in FIG. 15, once the
OBEX connection is set, a disconnection button B4 is
activated. When the user operates the disconnection
button B4, the image acquisition request unit 9600 .
20 utilizes the wireless communication management unit
9500 to disconnect from the currently connected
apparatus.

For the apparatus 9000, the following have been
shown: the method of setting an OBEX connection,
25 the method of deactivating the OBEX connection, the
method of acquiring a monitoring image, the method of
acquiring an identifier for an image, and the method of

acquiring the corresponding image on the basis of the identifier for the image. These methods conform to the Bluetooth BIP.

5 The apparatus 1000 is assumed to provide services and to be placed in the ship A. It is further assumed that the image storage unit 100 stores a plurality of images as advertisement information on the shop A. If the apparatus 9000 is connected to the apparatus 1000 utilizing the BIP remote camera feature, the
10 apparatus 1000 provides the apparatus 1000 with images stored in the storage unit 100, using the method described in the first, second, third, fourth, or fifth embodiment. In response to a GetMonitoringImage request with the store flag set to 0, i.e. a request
15 for the acquisition of a monitoring image which request is sent by the apparatus 9000, the apparatus 1000 selects one of the saved images and provides the apparatus 9000 with a thumbnail of the selected image. On the other hand, in response to a GetMonitoringImage
20 and GetImage requests with the store flag set to 1, the apparatus 1000 can provide a requested image of its original size. In this case, the apparatus 1000 can utilize the functions of the present invention to provide monitoring images at a rate of an appropriate
25 time per an image. For example, this embodiment of the present invention can avoid the following situation: if the apparatus 9000 outputs several requests for the

acquisition of a monitoring image within one second,
the apparatus 1000 provides the apparatus 9000 with
several different images within one second, so that the
user of the apparatus 9000 cannot check the contents
5 of the monitoring images. Moreover, while the user
of the apparatus 9000 is checking shop advertisement
information as monitoring images, if the user
determines that the information is useful and requests
the original image data to be acquired, the apparatus
10 1000 can correctly provide the images requested by the
user of the apparatus 9000. This avoids the following
situation: images unexpected by the user are provided
at some points in time.

Therefore, the sixth embodiment of the present
15 invention enables the construction of an advertisement
information providing server that can easily provide
advertisement information to apparatuses comprising
a function of initiating the BIP remote camera feature.
(Seventh Embodiment)

20 A seventh embodiment of the present invention will
be described below. If the Bluetooth is utilized, then
according to the Bluetooth specifications, an apparatus
called a "master" can be connected to an apparatus
called a "slave" and one master can be connected to
25 seven slaves to generate a piconet. The relationship
between the master and the slave is a link connection
that is a lower stack according to the Bluetooth and is

independent of an OBEX connection that is an upper stack according to the Bluetooth.

In the sixth embodiment, it is assumed that when the apparatus 9000 creates an OBEX connection to the apparatus 1000, the apparatus 9000 acts as a master, while the apparatus 1000 acts as a slave, according to the Bluetooth. However, in the present embodiment, the following method will be specifically described. The apparatus 1000 acts as a master, while the apparatus 9000 acts as a slave. A link connection that is a lower stack according to the Bluetooth is established. Then, the apparatus 9000 sets an OBEX connection to the apparatus 1000, the OBEX connection being an upper stack according to the Bluetooth. The apparatus 9000 then performs operations such as the acquisition of a monitoring image.

In the example of the operation screen provided by the display unit 9700 as shown in FIG. 15, when the user operates the discovery button B1 to display information on peripheral apparatus, selects the apparatus 1000, and then operates the connection button B3, the display unit 9700 outputs a connection request to the image acquisition request unit 9600. Upon receiving the inputted connection request, the image acquisition request unit 9600 registers a "connection service" for the apparatus 1000 in the wireless communication management unit 9500. The "connection

service" is assumed to be a service record containing service information utilized in the Service Discovery Protocol (SDP), included in the Bluetooth protocol stack. The registration of the "connection service" for the apparatus 1000 means that at least a service record containing the information "apparatus 1000" is newly registered in an SDP processing unit. Once the "connection service" for the apparatus 1000 is registered, the wireless communication management unit 9500 is brought into a standby state.

On the other hand, the apparatus 1000 is assumed to have a function of periodically acquiring service information from peripherally present apparatuses in accordance with the SDP. The apparatus 1000 acquires service information from the apparatus 9000. If the information acquired indicates a connection to the apparatus 1000, the apparatus 1000 acts as a master to make a connection to the apparatus 9000. When the apparatus 1000 is connected to the apparatus 9000, the wireless communication management unit 9500 of the apparatus 9000 recovers from the standby state. The wireless communication management unit 9500 then acts as slave to notify the image acquisition request unit 9600 of this connected state. When notified of the connected state, the image acquisition request unit 9600 inputs an OBEX connection request to the wireless communication management unit 9500. The image

acquisition request unit 9600 subsequently performs operations such as the acquisition of a monitoring image as in the case with the sixth embodiment.

In this case, communication is continued with the
5 apparatus 1000 acting as a master and the apparatus 9000 acting as a slave.

If in the standby state, a specified time or more has passed, the wireless communication management unit 9500 determines that the attempt to establish
10 a connection has failed. When notified of the failure, the image acquisition request unit 9600 displays an indication of the failure in the display area of the display unit 9700.

The difference between the sixth embodiment and
15 the seventh embodiment is that the apparatus 1000 acts as a slave or a master. When the apparatus 1000 acts as a master, it can be connected to plural slave apparatuses. Thus, if the apparatus 1000 is an advertisement information providing server that can
20 provide advertisement information, it is possible to form a piconet and simultaneously provide advertisement information to the plural slave apparatuses. When the apparatus 1000 simultaneously provides advertisement information to plural apparatuses, the image providing
25 method according to the present invention can be utilized to provide appropriate images as shown in the sixth embodiment.

Additional advantages and modifications will readily occur to those skilled in the art. Therefore, the invention in its broader aspects is not limited to the specific details and representative embodiments shown and described herein. Accordingly, various
5 modifications may be made without departing from the spirit or scope of the general inventive concept as defined by the appended claims and their equivalents.
